

Problem - Solution Fit

Validate that the proposed automation directly addresses the observed incident-management problems

DATE	STUDENT NAME	PROJECT
07 October 2026	Gangadevi.R	Incident Life Cycle Automation

Parameter	Project Fit
Target user	Incident process participants: reporters, support engineers, incident managers and auditors
Core problem	Manual or fragmented incident handling causes delays, unclear ownership, missed SLA actions and weak traceability.
Existing workaround	Email/chat/manual trackers and repeated follow-ups can coordinate the work, but the lifecycle remains fragmented.
Proposed solution	One rule-driven workflow that creates, routes, tracks, escalates, resolves and closes incidents while maintaining history.
Key trigger	A new incident, ownership change, approaching SLA, SLA breach, resolution submission or closure confirmation.
Behavior to leverage	Users already need to log, update, assign, monitor and review incidents; automation connects these actions rather than adding a separate process.
Expected value	Faster routing, visible ownership, earlier escalation, consistent status updates and audit-ready history.
Fit test	Each major automation maps to a known lifecycle pain and produces an observable operational outcome.

Problem-Solution Fit checklist

- Solves a frequent operational problem: yes - incident handling happens repeatedly.
- Fits existing behavior: yes - automation supports the same intake, triage, assignment, resolution and review activities.
- Creates measurable benefit: yes - ownership time, SLA risk and lifecycle visibility can be tracked.
- Avoids unnecessary scope: the initial build stays focused on the incident lifecycle workflow.
